COHOMOLOGY OF AFFINE DELIGNE-LUSZTIG VARIETIES FOR GL$_2$

A. IVANOV

ABSTRACT. In this paper we study affine Deligne-Lusztig varieties $X_w(b)$ for GL$_2$ and their étale coverings. At first, we compute them explicitly, then we determine associated representations of a certain locally-compact group, the group of rational points of the $\sigma$-stabilizer of $b$, in their étale cohomology. Further, we study these representations by determining morphisms into the irreducible representations of the given group. In particular all cuspidal representations of level 0 of GL$_2$ of a local field and of its inner form, which is the group of units of a quaternion algebra, occur in the cohomology.

1. INTRODUCTION

Let $k$ be a field with $q$ elements, and let $\bar{k}$ be an algebraic closure of $k$. Let $k \subset k' \subset \bar{k}$ be the quadratic extension of $k$ in $\bar{k}$. Let $\sigma$ denote the Frobenius morphism of $\bar{k}/k$. Put $F = k((t))$ and $L = \bar{k}((t))$. We extend $\sigma$ to the Frobenius morphism of $L/F$ by setting $\sigma(t) = t$. Write $\sigma = \bar{k}[[t]]$, $\sigma_F = k[[t]]$ and $p$, $p_F$ for valuation rings of $L$ resp. $F$ and for their maximal ideals. Denote the valuation on $L$ by $v_L$.

Let $G$ be a split connected reductive group over $k$ and let $T$ be a split maximal torus in $G$. For a coroot $\lambda \in X_*(T)$ we write $t^\lambda$ for the image of $t$ under $\lambda: \mathbb{G}_m \to T$. Write $W$ and $\tilde{W} = X_*(T) \rtimes W$ for the finite and the extended affine Weyl groups attached to $T$.

Fix a Borel subgroup $B$ containing $T$, such that $B = TU$ with $U$ unipotent. Let $I$ resp. $I_1$ be the preimage of $B(\bar{k})$ resp. $U(\bar{k})$ under the projection $G(\bar{k}) \to G(\bar{k})$. Then $I$ is an Iwahori subgroup in $G(L)$. Let $X = G(L)/I$ be the affine flag manifold and $X$ its covering $\tilde{X} = G(L)/I_1$. The group $G(L)$ acts by left translation on $X$ and $\tilde{X}$. The Bruhat decomposition implies that $G(L)$ is the union of the double cosets $IwI$, where $w \in \tilde{W}$. Put $T_1 := T(\sigma) \cap I_1$ and set $\tilde{W}_1 = N_G(T)(L)/T_1$. Then $G(L) = \coprod_{w \in \tilde{W}_1} I_1 \tilde{w} I_1$ (Lemma 3.1). Following [8], the affine Deligne-Lusztig variety $X_w(b)$ attached to $b \in G(L)$ and $w \in \tilde{W}$ is the locally closed subset of $X$, endowed with its reduced induced sub-Ind-scheme structure, defined by

$$X_w(b) = \{xI \in G(L)/I : x^{-1}b\sigma(x) \in IwI\}.$$ 

In analogy with [2], for $b \in G(L)$ and $\tilde{w} \in \tilde{W}_1$, we let $\tilde{X}_w(b)$ be the locally closed subset

$$\tilde{X}_w(b) = \{xI_1 \in G(L)/I_1 : x^{-1}b\sigma(x) \in I_1 \tilde{w} I_1\}$$

of $\tilde{X}$, endowed with its reduced induced sub-Ind-scheme structure. If $w \in \tilde{W}$ is the image of $\tilde{w}$, then the obvious projection map $\pi: \tilde{X}_w(b) \to X_w(b)$ is a finite étale torsor under the group $T(w)_{\text{aff}}^a/T_1 = \{a \in T(\sigma) : a^{-1}\text{ad}(w)(\sigma(a)) \in T_1\}/T_1$. The group

$$J_b = \{g \in G(L) : g^{-1}b\sigma(g) = b\}$$

acts by left multiplication on $X_w(b)$ and $\tilde{X}_w(b)$, and $\pi$ is $J_b$-equivariant.

Our first goal is to study these varieties in the case $G = GL_2$. In [10] Reuman determined the set $\{w \in \tilde{W} : X_w(b) \neq \emptyset\}$ for reductive groups of semisimple rank 1 and 2, and in particular for GL$_2$. We determine (in [2] and [3]) the precise structure of $X_w(b)$ and $\tilde{X}_w(b)$ as schemes locally of finite type over $k$. If $X_w(b) \neq \emptyset$, there are $J_b$- and $T(w)^a_{\text{aff}}/T_1$-equivariant (the actions on the right side are defined later) $\bar{k}$-isomorphisms:
\[ X_w(b) \cong \prod_{J_b / K_b^{(m)}} K_{b,w}^{d_{b,w}} \times S(b, w) \quad \text{and} \quad \dot{X}_w(b) \cong \prod_{J_b / K_b^{(m)}} K_{b,w}^{d_{b,w}} \times \dot{S}(b, w), \]

where the numbers \( m \in \{0, 1\}, d_{b,w} \geq 0 \) depend on \( b \) and \( w \) (cf. Section 3.3 for explicit formulas).

Let \( b_1 = \begin{pmatrix} 0 & 1 \\ t & 0 \end{pmatrix} \) and \( w_u := w_{b_1^{-1}v_L(\text{det}(b))} \in W_a \), where \( W_a \) is the affine Weyl group of \( T \cap G_{\text{der}} \) in \( G_{\text{der}} \), which is a Coxeter group equipped with a length function. Then we have:

\[
\begin{array}{|c|c|c|c|c|}
\hline
b & \ell(w_u) & J_b & K_b^{(m)} & S(b, w) \ widen \dot{S}(b, w) \\
\hline
1 & 0 \text{ or odd} & G(F) & b_1^m K b_1^{-m} & X_{w_{\text{fin}}} \ widen \dot{X}_{\text{fin}} \\
\ell(0, \alpha), \alpha > 0 & \alpha & T(F) & T(\s_o F) & \{pt\} \ widen \prod_{\mathcal{L}(k)} \{pt\} \\
\ell(1, \alpha), \alpha > 0 & \ell(w_u) - \alpha > 0 \text{ odd} & T(F) & T(\s_o F) & \overline{G}_m \ widen \prod_{k^*} \overline{G}_m \\
b_1 & \text{even} & D^* & U_D & \{pt\} \ widen \prod_{\mu_{2,1}} \{pt\} \\
\hline
\end{array}
\]

**Table 1.** Affine Deligne-Lusztig Varieties for \( GL_2 \)

In this table \( K = G(\s_o F) \), \( \dot{X}_{\text{fin}} \in G(k) \) lies over the image \( w_{\text{fin}} \) of \( w \) in \( W \) and \( X_{w_{\text{fin}}} \ widen \dot{X}_{\text{fin}} \) denote the corresponding finite Deligne-Lusztig varieties for \( G = GL_2 \). We have \( w_u \in W_a \) since \( X_w(b) \neq \emptyset \). Further, \( D \) denotes the central division algebra over \( F \) of dimension 4 and \( U_D \) the group of units in its valuation ring.

Since \( X_w(b) \) and \( \dot{X}_w(b) \) depend only on the \( \s \)-conjugacy class and also (essentially) only on the class modulo center of \( b \), all essential cases are presented in the table above (every element of \( G(L) \) is \( \s \)-conjugate to one of the \( b \)'s in the table multiplied by a central element).

Our second goal is to determine the representations of the locally profinite groups \( J_b \) in the cohomology of these varieties for \( G = GL_2 \). In analogy to [2], for any \( G \) and for a character \( \theta \) of \( T(w)_{\text{aff}} / T_1 \) define \( R_b^\theta(w)_{\text{aff}} \) to be the virtual \( J_b \)-representation

\[ R_b^\theta(w)_{\text{aff}} = \sum_i (-1)^i H_c^i(\dot{X}_w(b), \overline{G})_\theta. \]

For \( w_{\text{fin}} \in W \), let \( R_b^\theta(w_{\text{fin}}) \) denote the virtual representation of \( G(k) \) defined in [2] as the alternating sum of the \( G(k) \)-representations \( H_c^i(\dot{X}_{w_{\text{fin}}}, \overline{G})_\theta \), where \( \theta \) is a character of \( T(w_{\text{fin}})^\sigma = \{ t \in T(\dot{k}) : \text{ad}(w_{\text{fin}}) \sigma(t) = t \} \). Let now \( G = GL_2 \) and assume without loss of generality that \( T \) is the diagonal torus. For any \( w \in \dot{W} \) with image \( w_{\text{fin}} \in W \), we have:

\[ T(w_{\text{fin}})^\sigma = T(w)_{\text{aff}} / T_1 \cong \begin{cases} T(k) & \text{if } w_{\text{fin}} = 1, \\ k^* & \text{if } w_{\text{fin}} \neq 1, \end{cases} \]

the second isomorphism being given by reduction modulo \( p \). For \( m \in \{0, 1\} \) let \( p_m : K_b^{(m)} \to G(\dot{k}) \) be conjugation with \( b_1^m \) composed with reduction modulo \( p \). For \( b = 1 \) it maps \( K_b^{(m)} \) onto \( G(k) \), for \( b = \ell(0, \alpha) \) (\( \alpha > 0 \)) it maps \( K_b^{(m)} = T(\s_o F) \) onto \( T(k) \) and for \( b = b_1, p_m(K_b^{(m)}) \) projects onto \( k^* \), embedded in \( G(\dot{k}) \) by \( a \mapsto \text{diag}(a, a^2) \). If \( \pi \) is some representation of \( \text{im}(p_m) \), then we write \( \pi_{K_b^{(m)}} \) for the \( K_b^{(m)} \)-representation obtained by inflation via \( p_m \).

**Theorem 1.1.** Assume \( b \in G(L), w \in \dot{W} \) are such that \( X_w(b) \neq \emptyset \). Let \( \theta \) be a character of \( T(w)_{\text{aff}} / T_1 \).

(i) Let \( w_{\text{fin}} \) be the image of \( w \) in \( W \). Then:

\[ R_1^b(w)_{\text{aff}} = c\text{-Ind}_{K_b^{(m)}}^{G(F)} R_1^\theta(w_{\text{fin}})_{K_1^{(m)}}. \]
(ii) Let \( b = t^{(0,\alpha)} \) with \( \alpha > 0 \). Then:
\[
R^\theta_b(w)_{\text{aff}} = \begin{cases} 
\text{c-Ind}_{T(o_F)}^{T(F)} \tilde{\theta} & \text{if } \ell(w_a) = \alpha, \\
0 & \text{otherwise},
\end{cases}
\]
where \( \tilde{\theta} \) is either \( \theta \) or \( \theta^v \), where \( v \neq 1 \in W \).

(iii) Let \( b = b_1 \). Then \( T(w)_{\text{aff}} / T(I) \cong k^* \) and we have:
\[
R^\theta_{b_1}(w)_{\text{aff}} = \text{c-Ind}_{U_{o_D}}^{D^*} \theta_{U_D}.
\]

Part (ii) was already studied for \( GL_n \) for any \( n \). In particular, He proved in [3] Cor 11.11 that \( T(o_F) \) acts trivial on the Borel-Moore homology of \( X_w(b) \) for \( b \) regular element in \( T(L) \) and for any \( w \in W \). Also, for such \( b \)'s, Zbarsky determined in [12] the representations on the Borel-Moore homology of \( X_w(b) \) for \( SL_2 \) and \( SL_3 \).

Let us now restrict attention to the case \( b = 1 \). The representations of \( J_1 = G(F) \) contained in \( R^\theta_1(w)_{\text{aff}} \) are compact inductions from \( K \) (or its conjugate) to \( G(F) \) of all irreducible representations of \( G(k) \). Our last goal is to study them (Theorem 4.3) by determining the homomorphisms into the smooth irreducible representations of \( G(F) \), which are classified in [1]. In particular, if there are non-zero homomorphisms from \( c\text{-Ind}_K^{G(F)} \rho_K \) into \( \pi \) (with \( \pi, \rho \) irreducible) then \( \pi \) is of level zero (for a definition see [1] 12.6) and \( \pi \) and \( \rho \) are (with two exceptions) of the same “type”, that means, either both characters, or both twisted Steinberg representations or both principal series or both cuspidal. For a precise statement see Theorem 4.3. A similar picture is obtained for \( b = b_1 \) (Theorem 4.10).

The representations \( c\text{-Ind}_K^{G(F)} \rho_K \) are very big, in particular they are not admissible (cf. Remark 3). Dividing out the center (i.e. changing to \( PGL \) as presented in [3] and Remarks 3), 5 one obtains admissible representations. The representations obtained in this way for \( b = 1 \) resp. \( b = b_1 \) are more convenient: in particular we get all cuspidal representations of \( G(F) \) resp. \( D^* \) of level 0, whose central character is trivial on \( t^{(1,1)} \).

2. Affine Deligne-Lusztig varieties for \( GL_2 \)

From now on we permanently assume \( G = GL_2 \). Without loss of generality we choose \( T \) to be the diagonal torus and \( B \) the Borel subgroup of upper triangular matrices.

2.1. Further preliminaries.

2.1.1. Affine flag manifold. We regard \( X, \hat{X} \) as \( \text{Ind} \)-schemes in the usual way. The surjection \( \nu_L \circ \det: G(L) \to \hat{W} \) induces surjections \( X \to Z, \hat{X} \to Z \) and \( \hat{W} \to \hat{Z} \). We denote all these maps by \( \eta_G \). The fibers of \( \eta_G: X \to \hat{Z} \) resp. \( \eta_{\hat{G}}: \hat{X} \to Z \) are the connected components of \( X \) resp. \( \hat{X} \). Recall that \( W_a \) is the affine Weyl group of \( T \cap G_{\text{der}} \) in \( G_{\text{der}} = SL_2 \). There is a natural exact sequence
\[
1 \to W_a \to \hat{W} \overset{\eta_{\hat{G}}}{\to} Z \to 1.
\]
The group \( W_a \) is a Coxeter group and we denote by \( \ell(w) \) the length function on it. We fix a splitting of the above exact sequence sending 1 to \( b_1 \), where
\[
b_1 := \begin{pmatrix} 0 & 1 \\ t & 0 \end{pmatrix}.
\]
Note that \( b_1^{2m} \) is central in \( G(L) \) for \( m \in \mathbb{Z} \).

2.1.2. Bruhat-Tits building. We write \( \mathfrak{B}_\infty \) for the Bruhat-Tits building for \( G_{\text{der}}(L) \) and \( \mathfrak{B}_1 \) for the Bruhat-Tits building for \( G_{\text{der}}(F) \), where \( G_{\text{der}} = SL_2 \). Then \( \mathfrak{B}_1 \) is in a natural way a full subcomplex of \( \mathfrak{B}_\infty \). The choices of \( T_{\text{der}} := T \cap G_{\text{der}} \) and \( I_{\text{der}} := I \cap G_{\text{der}}(L) \) determine an apartment \( A_M \) and a base alcove \( C^0 \) lying in \( A_M \). Further, \( W_a \) acts simply transitively on the set of alcoves in \( A_M \). We fix an identification of \( W_a \) with this set by letting \( W_a \) act on \( C^0 \).
Furthermore, $\mathfrak{B}_\infty$ admits a description in terms of $k[[t]]$-lattices. Its vertices correspond to homothety classes of $k[[t]]$-lattices. Two vertices are connected by an alcove (1-dimensional simplex) if and only if there are representing lattices $\mathfrak{L}, \mathfrak{L}'$ with $t\mathfrak{L} \subseteq \mathfrak{L}' \subseteq \mathfrak{L}$. We denote by $H$ the stabilizer of determinant equal 0. Using the inclusion $G \subseteq H$, we can canonically identify of $W_a$ with $A_M$, $t^{-i} e_i = (t^{-i} 0 \ 0 \ t^{-i})$ corresponds to $C_{2i-1}$ for $i \in \mathbb{Z}$. In particular, if $wC_0 = C^r$, then $\ell(w) = |r|$. Via the above description $G(L)$ acts naturally on $\mathfrak{B}_\infty$, but this action is not type-preserving.

We denote by $H$ the stabilizer of determinant equal 0. Using the inclusion $G_{der}(L)/I_{der} \cong H/I \rightarrow G(L)/I = X$, the $k$-points of $\eta_G^{-1}(0) \subset X$ can canonically be identified with the alcoves in $\mathfrak{B}_\infty$ and with right cosets $H/I$. We will use this implicitly. Notice that $H$ is the maximal subgroup of $G(L)$, such that the above inclusion $\{\text{alcoves in } \mathfrak{B}_\infty \} \rightarrow X(\bar{k})$ is $H$-equivariant.

For $m \in \{0, 1\}$ denote by $P_m$ the vertex of $\mathfrak{B}_\infty$ represented by the lattice $\mathfrak{o} \oplus t^m \mathfrak{o}$. Then $P_0, P_1$ are the two vertices of $C_0$.

### 2.1.3. Vertex of departure

$\mathfrak{B}_\infty$ and $\mathfrak{B}_1$ are trees, i.e. connected one-dimensional simplicial complexes without cycles. A gallery with fixed first and last alcoves and minimal length is unique. Define the first vertex of a minimal gallery of positive length to be the unique vertex of its first alcove which is not a vertex of the second alcove. The relative position of two different alcoves in $\mathfrak{B}_\infty$ is determined by the length of the minimal gallery connecting them and the type of its first vertex.

Let $\mathfrak{C}$ be a full connected subcomplex of $\mathfrak{B}_\infty$ and $D$ be an alcove in $\mathfrak{B}_\infty$, which is not contained in $\mathfrak{C}$. Since $\mathfrak{B}_\infty$ is a tree and $\mathfrak{C}$ is connected, there is a unique gallery $\Gamma_{D, \mathfrak{C}}$ of minimal length in $\mathfrak{B}_\infty$ containing a vertex $P_D$ in $\mathfrak{C}$, whose first alcove is $D$. This vertex $P_D$ is unique.

**Definition 1.** Let $\mathfrak{C}, D, \Gamma_{D, \mathfrak{C}}$ and $P_D$ be as above. We call $P_D$ the vertex of departure for $D$ from $\mathfrak{C}$, and set

$$d_{\mathfrak{C}}(D) := 1 + \ell(\Gamma_{D, \mathfrak{C}}),$$

where $\ell(\Gamma)$ denotes the length of a gallery $\Gamma$.

In the situation as above, if additionally $m \in \{0, 1\}$ denote by $\mathfrak{C}^{(m)}$ the set of all vertices in $\mathfrak{C}$ with type $m$, and for $n > 0$ and $P$ a vertex in $\mathfrak{C}$ set

$$D^n_{\mathfrak{C}}(P) := \left\{ D : \begin{array}{l} D \text{ is an alcove in } \mathfrak{B}_\infty \text{ having } P \text{ as vertex of departure from } \mathfrak{C} \text{ and } d_{\mathfrak{C}}(D) = n \end{array} \right\} .$$

Assume for a moment, $\mathfrak{C} = \{C_0\}$ is the subcomplex consisting of the alcove $C_0$ and both of its vertices $P_0, P_1$. Then $D^n_{\{C_0\}}(P_m)$ is just the open Schubert cell inside the affine flag manifold $X^{der} \rightarrow G_{der}$, corresponding to the element $w \in W_0$ with $wC_0 = C^{(-1)m+n}$. Thus it is a locally closed subset of $X^{der} \cong \eta_G^{-1}(0)_{red}$ and with the reduced induced sub-Ind-scheme structure it is a $k$-scheme isomorphic to $\mathbb{A}^n$. If in addition $\mathfrak{C}$ contains some other alcoves $D_1, \ldots, D_r$ having $P_m$ as a vertex, then using the usual coordinates on an open Schubert cell in $X^{der}$, it is not hard to see that $D^n_{\mathfrak{C}}(P_m)$ is the open subset $\mathbb{A}^{n-1} \times (\mathbb{A}^1 - \{D_1, \ldots, D_r\})$ of $D^n_{\{C_0\}}(P_m) = \mathbb{A}^n$. If additionally $D_1, \ldots, D_r$ lie in $\mathfrak{B}_1$, then $D^n_{\mathfrak{C}}(P_m)$ is defined over $k$.

### 2.2. Some reductions.

Here we reduce the general setup to few computations in $\mathfrak{B}_\infty$.

**Lemma 2.1.** Let $b \in G(L)$ and $w \in \hat{W}$.

(i) For every $g \in G(L)$, the map $(h, x) \mapsto (g^{-1}hg, g^{-1}x)$ gives an isomorphism of pairs between $(J_h, X_w(b))$ and $(J_{g^{-1}bg}, X_w(g^{-1}bg)g))$.

(ii) If $X_w(b) \neq \emptyset$, then $\eta_G(b) = \eta_G(w)$.

(iii) Let $c \in G(L)$ be central and set $v = \eta_G(c)$. Then $X_w(b) = X_{wb^c}(cb)$.
Lemma 2.3. We see its points as alcoves in (ii) follows from (i) using the action of 
Proof. \(v\) \(H\) defined by Kottwitz in [7], and knowledge of the for example the second page of [3]. In our case however, it can also be seen explicitly, using the
\(\text{inv}(\cdot)\) is the multiplicative group \(D^*\) of the central division algebra \(D\) over \(F\) of dimension 4, and \(K_{b}^{(m)} = U_{D}\) is the unit subgroup of its valuation subring. The image of \(p_{m}\) is contained in \(B(\bar{k})\) and the image of \(p_{m}(U_{D})\) under projection \(pr: B(\bar{k}) \rightarrow T(\bar{k})\) is \(\{\text{diag}(a, a^0) : a \in k^{**}\} \cong k^{**}\). We write \(p'_{m} = pr \circ p_{m}\).

Lemma 2.2. Let \(b \in G(L)\) and \(w \in \tilde{W}\).
(i) The restriction of \(\eta_{G} : G(L) \rightarrow \mathbb{Z}\) to \(J_{b}\) is surjective.
(ii) We have:
\[X_{w}(b) \cong \bigoplus_{J_{b}/H_{b}} X_{w}(b) \cap \eta_{G}^{-1}(0),\]
where \(J_{b}\) acts on the set of these components by left multiplication.

Proof. (ii) follows from (i) using the action of \(J_{b}\) on \(X_{w}(b)\). (i) has a general proof, compare for example the second page of [3]. In our case however, it can also be seen explicitly, using the knowledge of the \(\sigma\)-conjugacy classes in \(G(L)\).

Lemma 2.2 holds also without the assumption \(G = GL_{2}\) (in general, one has the map \(\eta_{G} : G(L) \rightarrow \pi_{1}(G)\) defined by Kottwitz in [7], and \(H_{b}\) will be the kernel of the restriction \(\eta_{G} : J_{b} \rightarrow \pi_{1}(G)\)). Set
\[X_{w}^{0}(b) := X_{w}(b) \cap \eta_{G}^{-1}(0) \subseteq \eta_{G}^{-1}(0).\]
We see its points as alcoves in \(\mathcal{B}_{\infty}\).

Lemma 2.3. If \(x \in H/I\) corresponds to the alcove \(D\) in \(\mathcal{B}_{\infty}\), and \(w = w_{a}b_{1}^{v}\), with \(w_{a} \in W_{a}\) and \(v = \eta_{G}(b)\), then
\[xI \in X_{w}^{0}(b) \iff \text{inv}(D, b \cdot \sigma D) = w_{a},\]
where \(\text{inv}(\cdot, \cdot)\) denotes the relative position map on the alcoves in \(\mathcal{B}_{\infty}\) and \(g \cdot D\) denotes the action of \(G(L)\) on the alcoves in \(\mathcal{B}_{\infty}\).

Proof. Since \(b_{1} \cdot C^{0} = C^{0}\), we have \(b \cdot \sigma D = b \cdot \sigma(x)C^{0} = (b\sigma(x)b_{1}^{-v})C^{0}\) with \(b\sigma(x)b_{1}^{-v} \in H\). Thus:
\[xI \in X_{w}^{0}(b) \iff x^{-1}b\sigma(x) \in IwI \iff x^{-1}b\sigma(x)b_{1}^{-v} \in Iw_{a}I \iff \text{inv}(D, b \cdot \sigma D) = \text{inv}(xC^{0}, b\sigma(x)b_{1}^{-v}C^{0}) = w_{a}.\]

The following lemma is shown by Reuman in [10]. We include it only for completeness.

Lemma 2.4. (Non-emptiness of \(X_{w}(b)\)) Let \(b = \ell(0, \alpha)\) with \(\alpha \geq 0\) or \(b = b_{1}\) and \(w \in \tilde{W}\). Put \(w_{a} = wb_{1}^{-\eta_{G}(b)}\). Then \(X_{w}(b) \neq \emptyset\) if and only if \(w_{a} \in W_{a}\) and
(a) \(b = \ell(0, \alpha)\) and \(w_{a} \in W_{a}\) with \(\ell(w_{a}) - \alpha = 0\) or odd and positive, or
(b) \(b = b_{1}\) and \(\ell(w_{a})\) even.
3. Torsors over affine Deligne-Lusztig varieties and structure results

3.1. Bruhat decomposition for $\hat{X}$.

(All things said in this and in the beginning of the next subsection holds in the more general setting of the introduction, i.e., for any connected reductive $k$-group $G$.) Since $T_1 = T(\mathfrak{o}) \cap I_1$ is normal in $N_G(T)(L)$, we can consider the group $\tilde{W}_1$ defined by the exact sequence:

$$1 \to T_1 \to N_G(T)(L) \to \tilde{W}_1 \to 1$$

Given two elements $x, y \in N_G(T)(L)$ lying over the same element $\tilde{w}$ of $\tilde{W}_1$, the ratio $x^{-1}y$ lies in $T_1 \subset I_1$. Therefore $I_1 x I_1 = I_1 y I_1$. We denote this double coset by $I_1 \tilde{w} I_1$.

**Lemma 3.31.** We have the disjoint decomposition:

$$G(L) = \bigcup_{\tilde{w} \in \tilde{W}_1} I_1 \tilde{w} I_1.$$ 

**Proof.** Let $\tilde{v}$ run through a fixed system of representatives of $\tilde{W}$ in $N_G(T)(L)$ and $a$ through $T(\bar{k})$. Then $a \tilde{v}$ runs through a system of representatives of $\tilde{W}_1$. Since $\tilde{v}$ normalizes $T(\mathfrak{o})$ and since $I = I_1 \cdot T(\mathfrak{o}) = I_1 \cdot T(\bar{k})$, we have: $I \tilde{v} I = \bigcup_{a \in T(\mathfrak{o})} I_1 a \tilde{v} b I_1 = \bigcup_{a \in T(\mathfrak{o})} I_1 a \tilde{v} I_1$. From this and the usual Bruhat decomposition, it follows that $G(L) = \bigcup_{\tilde{w} \in \tilde{W}_1} I_1 \tilde{w} I_1$. It remains to show disjointness of two double cosets. First, $I_1 a_1 \tilde{v}_1 I_1 = I_1 a_2 \tilde{v}_2 I_1$ implies $I_1 \tilde{v}_1 I_1 = I_1 \tilde{v}_2 I_1$, hence $\tilde{v}_1 = \tilde{v}_2$. Thus (by replacing $\tilde{v}_1$ by $a_1 \tilde{v}_1$) it is enough to show that if $a \in T(\mathfrak{o})$ with $I_1 \tilde{v} I_1 = I_1 a \tilde{v} I_1$, then $a \in T_1$. But then there is an $i_1 \in I_1$, such that $i_1 a \in \tilde{v} I_1 \tilde{v}^{-1}$. But clearly $i_1 a \in I$, hence $i_1 a \in I \cap \tilde{v} I_1 \tilde{v}^{-1}$. Since $\tilde{v}^{-1} I_1 \tilde{v} \cong I_1$ has an (finite) filtration with subquotients isomorphic to $\bar{k}$, this intersection lies in $I_1$, the maximal subgroup of $I$ satisfying this property. Hence $a \in I_1 \cap T(\mathfrak{o}) = T_1$. \hfill $\square$

3.2. The varieties $\hat{X}_\tilde{w}(b)$.

3.2.1. Definition. The Frobenius $\sigma$ acts on $\hat{X}$. Therefore we can define:

**Definition 2.** Let $b \in G(L)$ and $\tilde{w} \in \tilde{W}_1$. We define $\hat{X}_\tilde{w}(b)$ to be the locally closed subset of $\hat{X}$ given by

$$\hat{X}_\tilde{w}(b) = \{ xI_1 \in G(L)/I_1 : x^{-1}b\sigma(x) \in I_1 \tilde{w} I_1 \}$$

provided with the reduced induced sub-Ind-scheme structure.

Moreover, $\hat{X}_\tilde{w}(b)$ is a $\bar{k}$-variety locally of finite type. The group $J_b$ defined in the introduction acts on $\hat{X}_\tilde{w}(b)$ by left multiplication. If $w$ is the image of $\tilde{w}$ in $W$, the forgetful morphism $\hat{X} \to X$ restricts to a $J_b$-equivariant morphism

$$\pi : \hat{X}_\tilde{w}(b) \to X_w(b).$$

We write $X_w(b)$ also for the base change of $X_w(b)$ to $\bar{k}$.

**Lemma 3.2.** Let $b \in G(L)$ and $\tilde{w} \in \tilde{W}_1$.

(i) For every $g \in G(L)$, the map $(h, x) \mapsto (g^{-1}hg, g^{-1}x)$ gives an isomorphism of pairs $(J_b, \hat{X}_\tilde{w}(b)) \cong (J_{g^{-1}b\sigma(g)}, \hat{X}_{g^{-1}\bar{k}(g)}(g^{-1}b\sigma(g)))$.

(ii) If $w$ is the image of $\tilde{w}$ in $W$, then $X_w(b) \neq \emptyset \iff X_w(b) \neq \emptyset$.

(iii) Let $\tilde{w}_1, \tilde{w}_2 \in \tilde{W}_1$ with the same image in $W$ and let $\tau$ be an element of $T(\mathfrak{o})$, such that $\tilde{w}_2 = \tilde{w}_1 \tau$ in $\tilde{W}_1$. There is a $\tau_1 \in T(\mathfrak{o})$, such that the right multiplication by $\tau_1$ induces a $J_b$-equivariant isomorphism

$$\tau_1 : \hat{X}_{\tilde{w}_1}(b) \cong \hat{X}_{\tilde{w}_2}(b), \quad \hat{x} I_1 \mapsto \hat{x} \tau_1 I_1.$$ 

**Proof.** (i) is straightforward. The one direction of (ii) is obvious, the other follows from (iii), since the preimage of $X_w(b)$ in $\hat{X}$ is equal to $\bigcup_{\tilde{w} \in \tilde{W}_1} \hat{X}_{\tilde{w}}(b)$. To prove (iii) let $w$ denote the image of $\tilde{w}_1$ in $W$. The equation $\tau_1^{-1} \text{ad}(w)(\sigma(\tau_1)) = \text{ad}(w)(\tau)$ in $T(\mathfrak{o})$ in the variable $\tau_1$ has a solution
in \( T(\sigma) \) for every \( \tau \), as follows from Hilbert’s Satz 90. For such a \( \tau_1 \) we have \( \tilde{\omega}_1 \tau = \tau_1^{-1} \tilde{\omega}_1 \sigma(\tau_1) \) in \( \tilde{W}_1 \). Hence if \( xI_1 \in \tilde{X}_\psi_1(b) \), then

\[
I_1(x\tau_1)^{-1}b\sigma(x)I_1 = I_1^{-1}x^{-1}b\sigma(x)\sigma(\tau_1)I_1 = \tau_1^{-1}I_1^{-1}x^{-1}b\sigma(x)I_1\sigma(\tau_1) = \tau_1^{-1}I_1 \tilde{\omega}_1 I_1 \sigma(\tau_1) = \]

\[
= I_1^{-1} \tilde{\omega}_1 I_1 \tau I_1 = I_1 \tilde{\omega}_1 I_1.
\]

Hence if \( xI_1 \in \tilde{X}_\psi_1(b) \), then \( x\tau_1 I_1 \in \tilde{X}_\psi_2(b) \). Thus \( \tau_1 \) gives a morphism from \( \tilde{X}_\psi_1(b) \) to \( \tilde{X}_\psi_2(b) \). Further, \( \tau_1^{-1} \) defines a morphism in the opposite direction and the two are inverses of each other. The \( J_b \)-equivariance is obvious.

3.2.2. Torus action. For \( \tilde{\omega} \in \tilde{W}_1 \), let \( \omega \) denote its image in \( \tilde{W} \). The right action of \( T(\sigma) \) on \( \tilde{X} \) restricts to an action of the group

\[
T(\omega)|_{\tilde{X}} = \{ \tau_1 \in T(\sigma) : \tau_1^{-1} \text{ad}(\omega)(\sigma(\tau_1)) \in T_1 \}
\]
on \( \tilde{X}_\psi(b) \). In fact, as in the proof of Lemma 3.2(iii), for \( \tau_1 \in T(\sigma) \) to send \( xI_1 \in \tilde{X}_\psi(b) \) to an element \( x\tau_1 I_1 \in \tilde{X}_\psi(b) \), it is necessary and sufficient that \( \tilde{\omega} \tau = \tilde{\omega} \) in \( \tilde{W}_1 \), where \( \text{ad}(\omega)(\tau_1) = \tau_1^{-1} \text{ad}(\omega)(\sigma(\tau_1)) \). This is equivalent to \( \tau \in T_1 \) and hence to \( \tau_1^{-1} \text{ad}(\omega)(\sigma(\tau_1)) = \text{ad}(\omega)(\tau_1) \in T_1 \). Obviously, \( T(\omega)|_{\tilde{X}} \supset T_1 \) and the action factorizes through \( T(\omega)|_{\tilde{X}} / T_1 \), which is finite. Let \( \omega_{\min} \) denote the image of \( \omega \) in \( W \). The adjoint action of \( W \) on \( T(\sigma) \) factorizes through \( W \), hence we only have two possibilities:

\[
T(\omega)|_{\tilde{X}} / T_1 = \begin{cases} T(k) \{ \text{diag}(a, a^q) \in T(k) : a \in k^* \} & \text{if } \omega_{\min} = 1, \\ \{ \text{diag}(a, a^q)\} & \text{if } \omega_{\min} \neq 1. \end{cases}
\]

In the last case, we use the identification \( T(\omega)|_{\tilde{X}} / T_1 \cong k^* \) by sending \( \text{diag}(a, a^q) \) to \( a \).

Remark 1. Since \( T(\sigma) \) is abelian, the isomorphism of Lemma 3.2(iii) is also \( T(\omega)|_{\tilde{X}} \)-equivariant.

3.3. Structure of \( X_w(b) \) and \( \tilde{X}_\psi(b) \). We explain now the precise structure of the varieties \( X_w(b) \) and \( \tilde{X}_\psi(b) \). First we introduce some notations. For \( b = t^{(0,\alpha)} \) with \( \alpha \geq 0 \) or \( b = b_1 \) and \( w \in \tilde{W} \), such that \( w_a := wb_1^{-\eta(b)} \in W_a \), let \( r \in \mathbb{Z} \) be such that \( w_a \) correspond to \( C^r \) (in particular, \( \ell(w_a) = |r| \)). Put:

\[
d_{b,w} := \begin{cases} \frac{\ell(w_a) - \alpha - 1}{2} & \text{if } b = t^{(0,\alpha)}, X_w(b) \neq \emptyset \text{ and } \ell(w_a) > \alpha \\ \frac{\ell(w_a)}{2} & \text{if } b = b_1 \text{ and } X_w(b) \neq \emptyset \\ 0 & \text{in all other cases}, \end{cases}
\]

\[
m := \begin{cases} 1 & \text{if } r - \text{sign}(r)\eta_{\mathbb{G}}(b) \equiv 1 \text{ mod } 4 \\ 0 & \text{otherwise}, \end{cases}
\]

\[
S(b, w) := \begin{cases} \mathbb{P}^1(k) & \text{if } b = 1, w_a = 1 \\ \mathbb{P}^1 - \mathbb{P}^1(k) & \text{if } b = 1, \ell(w_a) > 0 \\ \{ pt \} & \text{if } b = t^{(0,\alpha)} \text{ with } \alpha > 0, \ell(w_a) = \alpha \\ \mathbb{G}_{m} = \mathbb{P}^1 - \{ 0, \infty \} & \text{if } b = t^{(0,\alpha)} \text{ with } \alpha > 0, \ell(w_a) > \alpha \\ \{ pt \} & \text{if } b = b_1. \end{cases}
\]

Endow \( S(b, w) \) with left \( K_b^{(m)} \)-action as follows: first consider the \( p_m(K_b^{(m)}) \)-action on \( S(b, w) \), which is the restriction to \( p_m(K_b^{(m)}) \) of the \( G(\bar{k}) \)-action by linear transformations on \( \mathbb{P}^1 \) in the first, second and fourth cases above, and the trivial action in the third and the last case and then lift this to a \( K_b^{(m)} \)-action. This is enough to describe \( X_w(b) \).

Further, let \( w_{\min} \) denote the image of \( w \) in \( W \), and \( \tilde{w}_{\min} \) be a lift to \( G(\bar{k}) \). Recall that \( \tilde{X}_{w_{\min}} \) denotes the étale torsor over \( X_{w_{\min}} \) defined in [2]. We consider the following \( p_m(K_b^{(m)}) \)-equivariant finite étale torsor over \( S(b, w) \) with Galois group \( T(w)|_{\tilde{X}} / T_1 \):
Remark 2. \( \pi_{b,w} : \hat{S}(b, w) \to S(b, w) := \begin{cases} \hat{X}_{\psi_{\text{fin}}} \to X_{\psi_{\text{fin}}} & \text{if } b = 1 \\ T(k) \to \{pt\} & \text{if } b = t^{(0, \alpha)} \text{ with } \alpha > 0, \ell(w_{\alpha}) = \alpha \\ \prod_{\zeta \not\in c} \mathbb{G}_{m} \to \mathbb{G}_{m} & \text{if } b = t^{(0, \alpha)} \text{ with } \alpha > 0, \ell(w_{\alpha}) > \alpha \\ \mu_{q^{\alpha}-1} \to \{pt\} & \text{if } b = b_{1}, \end{cases} \)

where \( \pi_{b,w} \) is the usual projection in the first case, the constant map in the second and in the last case, and in the third case it sends \( x_{\zeta} \) to \( \zeta^{-1}x^{-q+1} \) (\( x_{\zeta} \) means the point \( x \) in the component \( \zeta \)). We explain now the \( p_{m}(K_{b}^{(m)}) \)- and \( T(w)^{\sigma}_{\text{aff}}/T_{1} \)-action on \( \hat{S}(b, w) \). If

\[
(b = t^{(0, \alpha)} \text{ and } b = \omega \text{ or } \frac{\ell(w) - \alpha + 1}{2} \in \mathbb{Z} \text{ is even}) \text{ or } (b = b_{1} \text{ and } \ell(w) \equiv 0 \text{ mod } 4),
\]

then the action is as follows: in the first case it is just the action of \( p_{m}(K_{b}^{(m)}) = G(\bar{k}) \) and of \( T(w)^{\sigma}_{\text{aff}}/T_{1} = T(w_{\text{fin}})^{\sigma} \) as in the finite Deligne-Lusztig theory. In the second resp. in the last case it is the multiplication action of \( T(w)^{\sigma}_{\text{aff}}/T_{1} = T(k) = p_{m}(K_{b}^{(m)}) \) resp. of \( T(w)^{\sigma}_{\text{aff}}/T_{1} = k^{*} = p_{m}(K_{b_{1}}^{(m)}) \) (this last has to be inflated to a \( p_{m}(K_{b_{1}}^{(m)}) \)-action). In the third case \( \text{diag}(g, h).x_{\zeta} = (g^{-1}x)_{g}h \) for \( \text{diag}(g, h) \in p_{m}(K_{b}^{(m)}) = T(k) \) and \( x_{\zeta}.\text{diag}(\tau, \tau^{q}) = (\tau^{-1}x)_{\tau^{q+1}} \) for \( \tau \in k^{*} \equiv T(w)^{\sigma}_{\text{aff}}/T_{1} \), in particular both actions induce via the determinant the same action of \( k^{*} \) on \( \pi_{0}(\hat{S}(b, w)) \). If condition (3.2) is not satisfied, then the action of \( p_{m}(K_{b}^{(m)}) \) is the same as above, but the action of \( T(w)^{\sigma}_{\text{aff}}/T_{1} \) is twisted by the adjoint action of \( \begin{pmatrix} 0 & 1 \\ 1 & 0 \end{pmatrix} \) on \( T(w)^{\sigma}_{\text{aff}}/T_{1} \). Finally, we lift the \( p_{m}(K_{b}^{(m)}) \)-action to an \( K_{b}^{(m)} \)-action.

Reduction modulo \( p \) gives natural embeddings \( p_{m}(K_{b}^{(m)}) \hookrightarrow G(\bar{k}) \twoheadrightarrow T(w)^{\sigma}_{\text{aff}}/T_{1} \). The “right” notion of an isomorphism between triples \( (\bar{S}_{i}, \alpha_{i}, \beta_{i}) \) \( i \in \{1, 2\} \) where \( p_{m}(K_{b}^{(m)}) \xrightarrow{\alpha_{i}} \text{Aut}(\bar{S}_{i}) \xleftarrow{\beta_{i}} T(w)^{\sigma}_{\text{aff}}/T_{1} \) are the actions, should be an isomorphism \( \phi : \bar{S}_{1} \sim \bar{S}_{2} \) together with an automorphism of \( G(\bar{k}) \), inducing automorphisms of \( p_{m}(K_{b}^{(m)}) \) and \( T(w)^{\sigma}_{\text{aff}}/T_{1} \), compatible with \( \phi, \alpha_{i} \) and \( \beta_{i} \). This reflects the fact that both actions have the same origin, being induced from the action of \( G(L) \) on \( X \).

**Theorem 3.3.** Let \( b = t^{(0, \alpha)} \) with \( \alpha \geq 0 \) or \( b = b_{1} \). Let \( w \in \hat{W}, \) such that \( X_{w_{\alpha}}(b) \neq \emptyset \). Then \( w_{\alpha} := w_{b_{1}}^{-1}g_{c}^{(b)} \in W_{a} \).

(i) (Structure of \( X_{w_{\alpha}}(b) \)) Let the alcove \( C^{\sigma} \) of \( A_{M} \) correspond to \( w_{\alpha} \). Then there are \( J_{b} \)-equivariant \( k \)-isomorphisms:

\[
X_{w_{\alpha}}(b) \cong \prod_{J_{b}/K_{b}^{(m)}} \mathbb{A}_{d_{b,w}}^{d_{b,w}} \times S(b, w),
\]

(ii) (Structure of \( \hat{X}_{w_{\alpha}}(b) \)) Let now \( \hat{w} \in \hat{W}_{1} \) be a preimage of \( w \) in \( \hat{W} \). Then there is a \( J_{b} \)- and \( T(w)^{\sigma}_{\text{aff}}/T_{1} \)-equivariant isomorphism

\[
\hat{X}_{w_{\alpha}}(b) \cong \prod_{J_{b}/K_{b}^{(m)}} \mathbb{A}_{d_{k,b}}^{d_{k,b}} \times \hat{S}(b, w),
\]

The \( J_{b} \)-equivariant morphism \( \pi : X_{w_{\alpha}}(b) \to X_{w_{\alpha}}(b) \) is finite étale with Galois group \( T(w)^{\sigma}_{\text{aff}}/T_{1} \), equal to the disjoint sum of the morphisms

\[
id_{d_{k,b}} \times \pi_{b,w} : \mathbb{A}_{k,b,w}^{d_{k,b,w}} \times \hat{S}(b, w) \to \mathbb{A}_{d_{k,b}}^{d_{k,b}} \times S(b, w).
\]

**Remark 2.** An easy computation shows that the non-emptiness and the dimension results fit into the conjectures 9.4.1 of [4].
Proof. (i): Lemma 2.1(ii) implies $X_w(b) \neq \emptyset \implies w_a \in W_a$. By Lemma 2.2 we are reduced to compute $X^0_w(b) := X_w(b) \cap \eta^{-1}_G(0)$, which can, at least set-theoretically, by Lemma 2.3 be identified with the set of alcoves $D$ in $\mathcal{B}_\infty$, such that the relative position of $D$ and $b \cdot \sigma D$ is $w_a$.

Case $b = 1$. Clearly, $\mathcal{B}_1$ is exactly the subcomplex of $\mathcal{B}_\infty$ stabilized by $\sigma$. Therefore, $X^0_w(1)$ is the disjoint union of points, indexed by alcoves in $\mathcal{B}_1$. Since $H_1$ acts on alcoves in $\mathcal{B}_1$ with stabilizer of $C^0$ equal $I \cap H_1$, we have:

$$X^0_w(1) = \coprod_{\text{alcoves in } \mathcal{B}_1} \{pt\} = \coprod_{H_1/I \cap H_1} \{pt\} = \coprod_{H_1/K \cap K/I \cap H_1} \{pt\}.$$ 

But $\coprod_{H_1/K \cap H_1} \{pt\}$ is together with its $K$-action isomorphic to $\mathbb{P}^1(k)$ with the $K$-action induced from the action of $G(k)$ by linear transformations. Now assume $1 \neq w \in W_a$. In the situation of 2.1.3 consider $\mathcal{C} = \mathcal{B}_1$. Let $D$ be an alcove in $\mathcal{B}_\infty$, not contained in $\mathcal{B}_1$. There is a unique gallery $\Gamma_{\mathcal{B}_1,D}$ of minimal length, equal $d_{\mathcal{B}_1}(D) - 1$, having $D$ as first alcove and containing a vertex in $\mathcal{B}_1$. Its image under $\sigma$ is again a gallery, containing the same vertex in $\mathcal{B}_1$ and it is easy to see that the composed gallery $\Gamma_{D,\sigma D} := (\Gamma_{\mathcal{B}_1,D}, \sigma \Gamma_{\mathcal{B}_1,D})$ is still minimal and connects $D$ with $\sigma D$. The length of this gallery is $2d_{\mathcal{B}_1}(D) - 1$, and hence the relative position of $D$ and $\sigma D$ is $C^{(-1)m(2d_{\mathcal{B}_1}(D) - 1)}$, where $m \in \{0, 1\}$ is the type of the first vertex of $\Gamma_{D,\sigma D}$ (note that $\Gamma_{D,\sigma D}$ is minimal and $\ell(\Gamma_{D,\sigma D}) > 0$, hence its first vertex is well-defined). In particular, $\ell(\Gamma_{D,\sigma D})$ is odd, which implies that if $D \in X^0_w(1)$, then $\ell(w)$ is odd. In particular, if $0 \neq \ell(w)$ is even, then $X_w(b) = \emptyset$ and if $\ell(w)$ is odd, then from the above description follows:

$$X^0_w(1) = \coprod_{P \in \mathcal{B}_1^{(m)}} D_{\mathcal{B}_1}(P),$$

with $m$ as in (3.1). Now $H_1 = G(F) \cap H$ acts naturally on $\mathcal{B}_1^{(m)}$ and the stabilizer of $P_m$ is $K_1^{(m)}$, hence canonically $H_1/K_1^{(m)} = \mathcal{B}_1^{(m)}$. By definition, $X_w(1)$ is given the reduced induced sub-Ind-scheme structure and as in 2.1.3 $D_{\mathcal{B}_1}(P) \cong H^{\ell(w) - 1}/H^{\ell(w) + 1}$, where $(\mathbb{P}^1 - \mathbb{P}^1(k))$ represents the alcoves having $P_m$ as a vertex and not lying in $\mathcal{B}_1$. Since $K_1^{(m)}$ is the stabilizer of $P_m$ in $H_1$, it acts on this $\mathbb{P}^1 - \mathbb{P}^1(k)$, and this action is the inflation via $p_m : K_1^{(m)} \twoheadrightarrow G(k)$ of the action of $G(k)$ on $\mathbb{P}^1 - \mathbb{P}^1(k)$ by linear transformations.

Case $b = t^{(0,\alpha)}$ with $\alpha > 0$. The element $t^{(0,\alpha)}$ acts on $A_M$ by shifting everything $\alpha$ alcoves to the right. In particular, if $D$ is an alcove in $A_M$, then the relative position of $D$ and $b \sigma D$ is $C^\alpha$ or $C^{-\alpha}$, which corresponds to an element $w_a \in W_a$ of length $\alpha$.

Consider now the situation as in 2.1.3 with $\mathcal{C} = A_M$ and any alcove $D$, not contained in $A_M$. Let $P_D$ be the vertex of departure for $D$ from $A_M$ and denote by $\Gamma_{\alpha,P_D}$ the minimal gallery connecting $P_D$ with its translate by $b$ (i.e. if $\alpha = 1$, this is the gallery with one alcove having $P_D$ and $b P_D$ as vertices, and if $\alpha > 1$, this is the unique gallery of minimal length, having $P_D$ as first vertex and $b P_D$ as last vertex). Then it is easy to see that the composed gallery $\Gamma_{D,\alpha,P_D} := (\Gamma_{D,A_M}, \Gamma_{\alpha,P_D}, b \sigma \Gamma_{D,A_M})$ is defined, and is the minimal gallery connecting $D$ with $b \sigma D$. We have $\ell(\Gamma_{D,\alpha,P_D}) = 2d_{A_M}(D) + \alpha - 1$, and in particular $\ell(\Gamma_{D,\alpha,P_D}) - \alpha$ is odd.

From all these we have for $w_a$ with $w_a C^0 = C^\alpha$:

$$X^0_w(b) = \coprod_{r \in \mathbb{Z}} \{C^{2r}\} = \coprod_{T(F) / T(\sigma F)} \{pt\}$$

and analogously for $w_a C^0 = C^{-\alpha}$. The rest of the proof, concerning the case $\ell(w_a) > 0$ works the same way as in the case $b = 1$, once one remarks that $A_M^{(m)}$ is naturally acted on by $H_b = T(F)$ with $K_b^{(m)} = T(\sigma F)$ being the stabilizer of $P_m$ (and also of any other point of $A_M^{(m)})$.

Case $b = b_1$. Take $\mathcal{C} = \{C^0\}$ (the full connected subcomplex with one alcove), $b_1$ acts on it by interchanging the both vertices $P_0$ and $P_1$. The stabilizer of $P_m$ is $H_{b_1} = K_{b_1}^{(m)} = U_D$. The arguments are similar to the both cases above and one obtains the whole open Schubert cell
\[ D_{\{0\}}^d(D_m) \text{ as } X_w^0(b_1), \text{ if } \ell(w) \text{ is even and the empty set otherwise. This completes the proof of (i).} \]

(ii): Using the \( J_\ell \)-action on \( \hat{X}_w^1 \text{ and the } J_\ell\text{-equivariant morphism } \pi: \hat{X}_w^1 \to X_w(b) \) we obtain from part (i) of the theorem that
\[
\hat{X}_w(b) = \prod_{J_b/K_m} \pi^{-1}(A_k^{d,2} \times S(b, w)).
\]

Thus we have to compute \( \pi^{-1}(A_k^{d,2} \times S(b, w)) \subseteq \hat{X}_w(b) \). We do this first in the case \( b = 1 \) and \( \ell(w) > 0 \) (since \( b = 1 \) and \( X_w(b) \neq \emptyset \), we have \( w_a = w \)) where \( A_k^{d,2} \times S(1, w) = D_{y_1}^{(w+1)}(P_m) \).

Write \( wC^0 = C_0^0 \) and assume \( m = 0 \) (the case \( m = 1 \) is similar). Then either \( r = -2i + 1 \) with \( i = 2n - 1 > 0 \) odd, or \( r = 2i - 1 \) with \( i = 2n > 0 \) even. For \( v \in W_a \) with \( vC_0^0 = C^{-1} \) we have \( D_{Y_1}^{(w+1)}(P_0) \subseteq I{vI}/I \). Consider first the case \( i = 2n - 1 \) odd, i.e. \( v = \begin{pmatrix} 0 & 0 \\ t^{1-n} & 1 \end{pmatrix} \).

By Lemma 3.2 (iii) we can assume \( \hat{w} = (0,0,0,0,0,0) \). Define affine coordinates on the preimage \( I{vI}/I_1 \) in \( \hat{X} \) of \( I{vI}/I \) by fixing the isomorphism \( \psi_{1,v}: A_k^{2n-1} \times G_2^m \to I{vI}/I_1 \),
\[
\psi_{1,v}((c_j)_{j=0}^{2n-2}, r, s) = \left( \begin{array}{ccc}
rc_t & st_{t+1} & 0 \\
t & t^{-1} & 0 \\
0 & 0 & 0
\end{array} \right) I_1.
\]

Write \( c = \sum_{j=0}^{2n-2} c_j t^{j-i(n-1)} \). We have \( \pi^{-1} \left( \begin{array}{c}
rc_t & st_{t+1} & 0 \\
t & t^{-1} & 0 \\
0 & 0 & 0
\end{array} \right) I_1 \). Then \( xI_1 := \left( \begin{array}{ccc}
rc_t & st_{t+1} & 0 \\
t & t^{-1} & 0 \\
0 & 0 & 0
\end{array} \right) I_1 \in \pi^{-1}(D_{y_1}^{(w+1)}(P_0)) \text{ in } \hat{X}_w(b) \Leftrightarrow I_1 x_1^{-1} \sigma(x) I_1 = I_1 \hat{w} I_1, \) which by a computation is equivalent to
\[
r_1 s^{q}(c_0 - c_0) = 1 \quad \text{and} \quad s^{-1} r^{q}(c_0^0 - c_0) = 1.
\]

which, after eliminating \( s = r^{q}(c_0^0 - c_0) \), is equivalent to \( r^{q}(c_0^0 - c_0) = 1 \). This last equation defines in the \( r-c_0 \)-plane a curve together with \( p_0(K_1^{(0)}) = G(k) \)-action isomorphic to the finite Deligne-Lusztig variety \( \hat{X}_w^1 \) for \( G \) over \( k \) with \( G(k) \)-action on it. The projection onto \( S(b, w) = \hat{X}_w^1 \) is given by \( (r, c_0) \mapsto c_0 \). The same is true for the other case \( i = 2n > 0 \) even, with \( v = t^{(n-n)} \), but \( xI_1 \) is then represented by \( \left( \begin{array}{ccc}
s & rc_t & st_{t+1} \\
0 & t & t^{-1} \\
0 & 0 & 0
\end{array} \right) \). In the first case the right \( T(w)^{q}_{\text{aff}}/T_1 = (w_a)^{q}_{\text{aff}} \)-action on our curve is given by \( (r, c_0) \cdot \text{diag}(\tau, \tau^q) = (\tau r, c_0) \) and in the second case by \( (r, c_0) \cdot \text{diag}(\tau, \tau^q) = (\tau^q r, c_0) \) and the \( p_m(K_1^{(0)}) \)-actions are equal in both cases.

This explains the twist of \( T(w)^{q}_{\text{aff}}/T_1 \)-action by \( \left( \begin{array}{ccc} 0 & 1 & 0 \\
1 & 0 & 1 \\
0 & 0 & 0
\end{array} \right) \) in the definition of \( S(b, w) \).

All other cases can be computed similar to the case above. Let us for example work out the case \( b = t^{(m)} \) with \( \alpha > 0 \) and \( \ell(w) > \alpha \). In this case \( A_k^{d,2} \times S(b, w) = D_{\alpha}^{(w_0)}(P_m) \).

Write \( w_0 C^0 = C_r^0 \) and assume \( m = 0 \) (the case \( m = 1 \) is similar). Then either \( r = -2i - 1 \) with \( i = 2n - 1 > 0 \) odd, or \( r = \alpha + 2i - 1 \) with \( i = 2n > 0 \) even. Consider only the first of this cases, the second being similar. We can assume \( \hat{w} = \left( \begin{array}{ccc} 0 & 0 & 0 \\
t^{1-i} & 1 & 0 \\
0 & t^{a+i} & 0
\end{array} \right) \). Let \( vC_0^0 = C^{-i} \), then \( D_{\alpha}^{(w_0)}(P_0) \) is the open subset in \( \hat{X}_w^1 \) on which \( c_0 \neq 0 \). Then \( xI_1 := \psi_{1,v}(c, r, s) \in \pi^{-1}(D_{\alpha}^{(t+1)}(P_0)) \text{ and } b\sigma(x) I_1 \) are in relative position \( \hat{w} \) if and only if \( I_1 x_1^{-1} b\sigma(x) I_1 = I_1 \hat{w} I_1 \) which is equivalent to
\[
r_1 s^{-1} q_0^{-1} = 1 \quad \text{and} \quad s^{-1} q_0^{-1} = 1.
\]
After eliminating $s = r^q c_0^q$, this is equivalent to $r^{2q-1}c_0^{q-1} = 1$. The locus of this equation in the affine plane with coordinates $r, c_0$ is the union of $q-1$ disjoint curves

\[ C_\beta = \text{Spec}(\bar{k}[v, c_0]/(r^{q+1}c_0^q - \zeta)) \hookrightarrow \text{Spec}(\bar{k}[z, z^{-1}]) \] with $\zeta \in k^*$,

where the isomorphism is on coordinates given by $(r, c_0) \mapsto (\zeta v, \zeta^{-1}z^{-(q+1)})$. The statements about the $p_m(K_b^{(m)} \text{-})$- and $T(w)^\sigma_{\text{aff}}$-actions can now be deduced explicitly from this description.

3.4. $PGL_2$ and admissibility.

Remark that $J_b \cap Z(G(L)) = Z(G(F))$. Denote this group by $Z$. Then $ZK_b^{(m)/K_b^{(m)}}$ is not compact, which is the reason, why the $J_b$-representations in the cohomology of $X_\hat{w}(b)$ for $b = 1, b_1$, considered in the next paragraph, are not admissible (see Remark 4). If one changes to $PGL_2$ (i.e. if one divides out the center), one obtains admissible representations (cf. Remark 3(i) for the case $b = 1$ and Remark 5 for the case $b = b_1$). Here we describe $X_w(b)$ and $X_{\hat{w}}(b)$ for $PGL_2$.

The affine flag manifold $X_{\text{PGL}}$ of $PGL_2$ is obtained from $X$ by identifying all odd and all even connected components $(\eta_2^{-1}(v))$ with $\eta_2^{-1}(v+2n)$ via multiplication with $(t^{(n,n)})$. The affine Weyl group $W_{\text{PGL}}$ of $PGL_2$ is the quotient of $W$ by the subgroup generated by $t^{(1,1)}$. If $w \in W$, write again $w$ for its image in $W_{\text{PGL}}$. We denote by

\[ X_w^{\text{PGL}}(b) \text{ and } \hat{X}_w^{\text{PGL}}(b) \]

the affine Deligne-Lusztig varieties associated to $PGL_2$. Then $J_b$ acts on $X_w^{\text{PGL}}(b)$ and $\hat{X}_w^{\text{PGL}}(b)$ through the quotient $J_b/Z$, which is the $\sigma$-stabilizer of $b$ in $PGL_2(L)$. Then $X_w^{\text{PGL}}(b)$ is exactly the image of $X_w(b)$ under the projection map $X \twoheadrightarrow X_{\text{PGL}}$.

Let $b = t^{(0,\alpha)}$ with $\alpha \geq 0$ or $b = b_1$ and $w \in \hat{W}$, such that $X_w(b) \neq \emptyset$. Extend the action of $K_b^{(0)}$ on $S(b, w)$, $\hat{S}(b, w)$ to an action of $ZK_b^{(0)}$ by letting $t^{(1,1)}$ act trivial. This action of $ZK_b^{(0)}$ factorizes through $r: ZK_b^{(0)} \rightarrow ZK_b^{(0)}/(t^{(1,1)}) \cong K_b^{(0)}$, and therefore through $pr: ZK_b^{(0)} \rightarrow p_0(K_b^{(0)})$.

Proposition 3.4. Let $b, w, \hat{w}$ be as in Theorem 3.3 Then there are the following $J_b$-equivariant (for the action defined above) isomorphisms:

\[ X_w^{\text{PGL}}(b) \cong \coprod_{J_b/ZK_b^{(0)}} \mathbb{A}^d_{k_b} \times S(b, w), \]

\[ \hat{X}_w^{\text{PGL}}(b) \cong \coprod_{J_b/ZK_b^{(0)}} \mathbb{A}^d_{k_b} \times \hat{S}(b, w). \]

The second isomorphism is $T(w)^\sigma_{\text{aff}}/T_1$-equivariant.

Proof. This follows by easy computations from Theorem 3.3 \hfill \square

4. Representation Theory of $J_b$

For a topological group $\Gamma$ we denote by $\hat{\Gamma}$ the set of classes of smooth irreducible $\Gamma$-representations over $\mathbb{Q}_l$. Further we define the cohomology with compact support of a colimit (which in our case is just a disjoint union) of schemes of finite type over $k$ as the colimit of the cohomology with compact support of these schemes. With this definition, the cohomology with compact support commutes with colimits.

4.1. Definition of $R_b^0(w)_{\text{aff}}$.

The groups $T(w)^\sigma_{\text{aff}}/T_1$ and $J_b$ act on $H^c_c(\hat{X}_0(b), \mathbb{Q}_l^e)$ by transport of the structure. As in \ref{1.8}, since $T(w)^\sigma_{\text{aff}}/T_1$ is abelian and since its action and that of $J_b$ commute (the first is a right and the second a left action), $H^c_c(\hat{X}_0(b), \mathbb{Q}_l^e)$ decomposes as the direct sum of the...
Jb-subrepresentations $H_c^r(\hat{X}_w(b),\overline{U_l})_\theta$ on which $T(w)_{aff}/T_1$ acts through the character $\theta \in T(w)_{aff}/T_1$. The following definition is the analogon in the affine case of \[2\] 1.9.

**Definition 3.** Let $b \in G(L)$ and $\hat{w} \in \hat{W}_1$ with image $w$ in $\hat{W}$, such that $X_w(b) \neq \emptyset$. Let $\theta \in T(w)_{aff}/T_1$ be a character. For $\ast$ either empty or PGL, define the virtual $J_b$-representation

$$R^\theta_b(w)_{aff,\ast} := \sum_r (-1)^r H_c^r(\hat{X}^*_w(b),\overline{U_l})_\theta$$

In the second case $J_b$ acts as explained in subsection 3.4.

This virtual representation is in fact independent of the choice of $\hat{w}$ lying over $w$ by Lemma 3.2 (which has an obvious extension to the case $\ast = \text{PGL}$).

**Lemma 4.1.** Let $b \in G(L)$ and $\hat{w} \in \hat{W}_1$ with image $w$ in $\hat{W}$, such that $X_w(b) \neq \emptyset$. Define

$$K_{b,\ast}^{(m)} = \begin{cases} K_{b}^{(m)} & \text{if } \ast = \text{empty} \\ ZK_{b}^{(0)} & \text{if } \ast = \text{PGL}. \end{cases}$$

Let $\theta \in T(w)_{aff}/T_1$. Then

$$H^r_c(\hat{X}^*_w(b),\overline{U_l})_\theta = c\text{-Ind}_{K_{b,\ast}^{(m)}}^{J_b} H^r_c(\hat{X}^{\ast}_{\hat{w}}(b),\overline{U_l})_\theta$$

where $K_{b,\ast}^{(m)}$-action on $\hat{S}(b,w)$ is the inflation of the $p_m(K_{b}^{(m)})$-action, and the $d_{b,w}$ in the brackets denotes the twist, defining the action of the Galois group of $\hat{k}/k$.

**Proof.** It follows by taking the $\theta$-isotypic components from

$$H^r_c(\hat{X}^*_w(b),\overline{U_l}) = H^r_c(\bigoplus_{b/K_{b,\ast}^{(m)}} K_{b,\ast}^{(m)} \times \hat{S}(b,w),\overline{U_l}) = c\text{-Ind}_{K_{b,\ast}^{(m)}}^{J_b} H^r_c(K_{b,\ast}^{(m)} \times \hat{S}(b,w),\overline{U_l})$$

$$= c\text{-Ind}_{J_b/K_{b,\ast}^{(m)}}^{J_b} H^r_c(\hat{S}(b,w),\overline{U_l}(d_{b,w})),$$

where the third equality is a consequence of the Künneth-formula. Second statement has a similar proof. \hfill $\square$

### 4.2. Case $b = 1$: Representation theory of $G(F)$.

#### 4.2.1. Over a finite field. The representation theory of $G = GL_2$ over a finite field is easy. We recall the irreducible representations to state our results. Let $\alpha, \beta \in \hat{k}^*$. There are the following four types of irreducible representations of $G(k)$:

- $\rho(\theta) := \text{Ind}^{G(k)}_{B(k)} \theta$, where $\theta = \alpha \otimes \beta$ is a character of the split torus $T(k) \cong k^* \times k^*$, such that $\alpha \neq \beta$ vary over $\hat{k}^*$. These are the principal series representations.
- $\alpha_{G(k)} := \alpha \circ \det$.
- $\alpha \cdot \text{St}(G(k))$, the $q$-dimensional twisted Steinberg representation defined through the following split exact sequence, where the first map is the diagonal embedding:

$$0 \rightarrow \alpha_{G(k)} \rightarrow \text{Ind}^{G(k)}_{B(k)} \alpha \rightarrow \alpha \cdot \text{St}(G(k)) \rightarrow 0.$$

- $\pi(\theta')$, the cuspidal representations, where $\theta'$ varies over characters of a non-split torus in $G(k)$ with $\theta' \neq \theta'^\vee$. Then $\pi(\theta') \equiv \pi(\theta'^\vee)$.

For $w_{\text{fin}} \in W$ and $\theta \in T(w_{\text{fin}})^{\sigma}$ Deligne and Lusztig defined in \[2\] the virtual representations $R^\theta(w_{\text{fin}})$, which for $G = GL_2$ are for example computed in \[11\].
4.2.2. Over \( F \). From the finite Deligne-Lusztig theory for \( G \) over \( k \) and from Lemma 4.1 we obtain (since \( \pi(\theta') \cong \pi(\theta'^\ell) \) for cuspidal representations of \( G(k) \), the ugly technical condition (3.2) is irrelevant):

**Corollary 4.2.** Let \( w \in \widehat{W} \), such that \( X_w(1) \neq \emptyset \), \( m \in \{0,1\} \) as in (3.1). Write \( w_{\text{fin}} \) for the image of \( w \) in \( W \) and let \( \theta \in T(w_{\text{fin}})^{\sigma}/T_1 = T(w_{\text{fin}})^\sigma \). For \( * \) either empty or PGL, let \( K_1^{(m)} \) be as in Lemma 4.1.

(i) If \( w = 1 \), then \( T(w_{\text{fin}})^{\sigma}/T_1 = T(k) \), and

\[
R^\theta_{1}(1)_{\text{aff}} = \begin{cases} 
\text{c-Ind}_{K_1^{(m)}}^{G(F)}(\rho(\theta)) & \text{if } \theta = \alpha \otimes \beta \text{ with } \alpha \neq \beta \\
\text{c-Ind}_{K_1^{(m)}}^{G(F)}(\alpha_{G(k)} + \alpha \cdot \text{St}_{G(k)}) & \text{if } \theta = \alpha \otimes \alpha.
\end{cases}
\]

(ii) If \( w \neq 1 \), then \( T(w_{\text{fin}})^{\sigma}/T_1 \cong k^{*} \), and

\[
R^\theta_{1, *}(w)_{\text{aff,*}} = \begin{cases} 
\text{c-Ind}_{K_1^{(m)}}^{G(F)}(\pi(\theta)) & \text{if } \theta \neq \theta^0 \\
\text{c-Ind}_{K_1^{(m)}}^{G(F)}(\alpha_{G(k)} - \alpha \cdot \text{St}_{G(k)}) & \text{if } \theta = \theta^0,
\end{cases}
\]

where \( \alpha(Nz) := \theta(z) \), where \( N \) denotes the norm of \( k'/k \).

**Remark 3.**

(i) If \( w \neq 1 \) the representations \( -R^\theta_{1}(w)_{\text{aff,PGL}} \) with \( \theta \neq \theta^0 \) run through all cuspidal \( G(F) \)-representations of level zero, whose central character is trivial on \( \ell \). In particular, they are admissible by [1] 11.4 Theorem and 10.2 Corollary (cf. also section 3.4).

(ii) If \( w \neq 1 \) and \( X_w(1) \neq \emptyset \), the \( G(F) \)-representations \( R^\theta_{1}(w)_{\text{aff}} \), \( R^\theta_{1}(w)_{\text{aff,PGL}} \) are independent of \( w \), which illustrates the general principle proved by He in [3] Cor. 4.8 that for \( \text{PGL}_n \), the representations occurring in the cohomology of \( X_w(1) \) for some \( w \), already occur in the cohomology of \( X_w(1) \) for \( w \) in the finite Weyl group. However, by Lemma 4.1 \( R^\theta_{1}(w)_{\text{aff}} \) comming from \( w \)'s with different length, differ as \( G(k'/k) \)-representations, since the numbers \( d_{1,w} = \ell(w_{\text{fin}}) - 1 \) (cf. (3.1)), defining the Tate twist, depend on \( \ell(w_{\text{fin}}) \).

Now we study morphisms from the representations occurring in \( R^\theta_{1}(w)_{\text{aff}} \) into smooth irreducible representations of \( G(F) \). These are described in [1]. Let us first fix some notation. We write \( \phi_{G(F)} := \phi \circ \det \), if \( \phi \in \widehat{F}^* \), and \( \phi \cdot \text{St}_{G(F)} \) for the corresponding twisted Steinberg representation. If a smooth irreducible representation \( \pi \) of \( G(F) \) contains the trivial character on a subgroup conjugate to \( \ker(p_0) : K \rightarrow G(k) \), then the level \( \ell(\pi) \) of \( \pi \) is 0 (loc.cit. 12.6). The levels of \( \phi_{G(F)} \) and \( \phi \cdot \text{St}_{G(F)} \) resp. \( \text{Ind}_{\overline{G(F)}}^{\overline{G(F)}}(\chi \in \overline{T}(F)) \) are zero if and only if the level of \( \phi \) resp. \( \chi \) is zero (this follows from loc.cit. 12.9 Theorem and 14.2 Theorem, which characterize representations of level > 0 as such, containing fundamental strata). The restriction of a character \( \phi \in \widehat{F}^* \) resp. \( \chi \in \overline{w} \cdot \hat{T}(F) \) of level zero to \( \sigma_1^* \) resp. \( T(\sigma_1^*) \) is an inflation of a character which we denote by \( \overline{\phi} \) resp. \( \overline{\chi} \) of \( k^* \) resp. \( T(k) \). Analogously the level of a cuspidal representation \( \phi \) is 0 if and only if its restriction to \( K \) contains an inflation of a (unique up to isomorphism) cuspidal representation \( \overline{\phi} \) of \( G(k) \).

Let \( u \) denote the non-trivial element of \( W \). Then if \( \lambda = \lambda_1 \otimes \lambda_2 \in \overline{T}(k) \), we write \( u \lambda := \lambda_2 \otimes \lambda_1 \). For simplicity we only handle the case \( m = 0 \). By abuse of notation, if \( \pi \) is any \( G(k) \)-representation, we write also \( \pi \) for its inflation via \( p_0 \) to \( K \).

**Theorem 4.3.** Let the first row (resp. first column) entries in the table below run through \( \overline{G(F)} \) (resp. through compact inductions of \( \overline{G(k)} \)) with \( \alpha \), \( \rho(\theta) \), \( \pi(\theta^0) \) as in 4.2.1 \( \chi \in \overline{T}(F) \), \( \phi \in \widehat{F}^* \) and \( \varphi \in \overline{G(F)} \) cuspidal as above. There are no non-zero homomorphisms from any left into any upper entry, unless the level of the upper entry is 0.

Assume that this holds and denote by \( \overline{\chi}, \overline{\phi} \), resp. \( \overline{\varphi} \) the corresponding representation of \( k^*, T(k) \), resp. \( G(k) \). The \( (i,j) \)-th entry in the table below is the space of all \( G(F) \)-homomorphisms from the representation in the \( i \)-th row into the one in the \( j \)-th column.
Also from Lemma 4.4 we have:

Proof of the lemma. Frobenius reciprocity implies:

\[
    \text{c-Ind}_K^G \rho(\theta) \quad \begin{cases}
    \varnothing  & \text{if } \check{\chi} = \theta \\
    \varnothing  & \text{or } \check{\chi} = \check{\psi} \\
    0        & \text{otherwise}
    \end{cases}
\]

\[
    \text{c-Ind}_K^G \theta_{G(k)} \quad \begin{cases}
    \varnothing  & \text{if } \check{\chi} = \check{\alpha}_{T(k)} \\
    \varnothing  & \text{or } \check{\phi} = \check{\alpha} \\
    0        & \text{otherwise}
    \end{cases}
\]

\[
    \text{c-Ind}_K^G \alpha \cdot \text{St}_{G(k)} \quad \begin{cases}
    \varnothing  & \text{if } \check{\chi} = \check{\alpha}_{T(k)} \\
    \varnothing  & \text{or } \check{\phi} = \check{\alpha} \\
    0        & \text{otherwise}
    \end{cases}
\]

\[
    \text{c-Ind}_K^G \pi(\theta') \quad \begin{cases}
    \varnothing  & \text{if } \check{\phi} = \pi(\theta') \\
    0        & \text{otherwise}
    \end{cases}
\]

Table 2. Morphisms into irreducible representations

Proof. First of all, if \( \pi \in \hat{G} \) and \( \rho \in \hat{G} \) with

\[0 \neq \text{Hom}_{G(F)}(\text{c-Ind}_K^G \pi, \rho) = \text{Hom}_K(\pi, \rho),\]

then \( \rho \) must contain the trivial character on \( \ker(p_0): K \rightarrow G(k) \), since \( \pi \) is inflated from \( G(k) \), and hence is trivial on this kernel. Therefore the statement about the levels follows and we can assume the levels of the representations in the upper row are 0. In particular, \( \phi|_{\sigma_F^i} \) resp. \( \chi|_{T(\sigma_F)} \) are inflations from \( k^* \) resp. \( T(k) \) of characters \( \check{\phi}, \check{\chi} \). Now we compute the places \((i,j)\) with \( 1 \leq i, j \leq 3 \).

Lemma 4.4. Let \( \pi \) be any \( G(k) \)-representation and \( \mu \in \hat{T(F)} \) of level 0, such that \( \mu|_{T(\sigma_F)} \) is induced from \( \bar{\mu} \in \hat{T(k)} \). Then

\[\text{Hom}_{G(F)}(\text{c-Ind}_K^G \pi, \text{Ind}_{B(F)}^G \mu) = \text{Hom}_{B(k)}(\pi, \bar{\mu}).\]

Proof of the lemma. Frobenius reciprocity implies:

\[\text{Hom}_{G(F)}(\text{c-Ind}_K^G \pi, \text{Ind}_{B(F)}^G \mu) = \text{Hom}_K(\pi, \text{Ind}_{B(F) \cap K}^B \mu) = \text{Hom}_{B(F) \cap K}(\pi, \mu),\]

where for the first equality we used the Mackey formula and \( B(F) \cdot K = G(F) \). Since inflation commutes with taking homomorphisms, we obtain:

\[\text{Hom}_{B(F) \cap K}(\pi, \mu) = \text{Hom}_{B(F) \cap K}(\text{Ind}_{B(k)}^B \pi, \text{Ind}_{B(k)}^B \mu) = \text{Hom}_{B(k)}(\pi, \bar{\mu}).\]

Apply the lemma to \( \pi = \text{Ind}_{B(k)}^G \lambda \) for some \( T(k) \)-character \( \lambda = \lambda_1 \otimes \lambda_2 \):

\[\text{Hom}_{G(F)}(\text{c-Ind}_K^G \pi, \text{Ind}_{B(F)}^G \mu) = \text{Hom}_{B(k)}(\pi, \bar{\mu}) = \text{Hom}_{B(k)}(\text{Ind}_{B(k)}^G \lambda, \bar{\mu}) = \text{Hom}_{T(k)}(\lambda, \bar{\mu}) \oplus \text{Hom}_{T(k)}(\bar{\mu}, \bar{\mu}),\]

where \( v \) is the non-trivial element of \( W \). In particular we obtain the \((1,1)\)-entry of the table by taking \( \lambda = \theta, \mu = \chi \). Put \( \phi_{T(F)} := \phi \circ \phi \in \hat{T(F)} \), \( \alpha_{T(k)} := \alpha \otimes \alpha \in \hat{T(k)} \). Then

\[\phi_{G(F)}|_K \oplus \phi \cdot \text{St}_{G(F)}|_K \cong \text{Ind}_{B(F)}^G \phi_{T(F)}|_K \quad \text{and} \quad \alpha_{G(k)} \oplus \alpha \cdot \text{St}_{G(k)} \cong \text{Ind}_{B(k)}^G \alpha_{T(k)},\]

(the first equality uses that \( K \) is compact and hence its representation theory is semisimple). Also from Lemma 4.4 we have:

\[\text{Hom}_{G(F)}(\text{c-Ind}_K^G \alpha_{G(k)}, \text{Ind}_{B(F)}^G \chi) = \text{Hom}_{B(k)}(\alpha_{G(k)}, \check{\chi}) = \text{Hom}_{T(k)}(\alpha_{T(k)}, \check{\chi})\]
which implies the (2,1)-entry. This, the second formula of (4.2) and (4.1) applied to \( \pi = \text{Ind}_{B(k)}^{G(k)} \alpha_{T(k)} \) and \( \mu = \chi \) imply also the (3,1)-entry. From (4.1) and the first formula of (4.2) the entries (1, 2) and (1, 3) follow.

Now we investigate the four squares in the middle of the table. Let us write \((i, j)\) for the \(\text{Hom}\)-space standing in the \((i, j)\)-place. Together with (4.2) and Lemma 4.4 an application of the Mackey formula as in (4.1) gives:

\[
(2, 2) \oplus (2, 3) \oplus (3, 2) \oplus (3, 3) = \text{Hom}_{T(k)}(\alpha_{T(k)}, \bar{\phi}_{T(k)}) \oplus \text{Hom}_{\tilde{T}(k)}(\alpha_{T(k)}, \bar{\phi}_{T(k)})
\]

\[
= \begin{cases} \mathbb{Q}_l & \text{if } \alpha = \bar{\phi}, \\ 0 & \text{otherwise}. \end{cases}
\]

In particular, we can assume that \( \alpha = \bar{\phi} \). It will suffice to show that \((2, 2), (2, 2) \oplus (2, 3) \) and \((2, 2) \oplus (3, 2) \) are one-dimensional. This is done by a (three) one-line computation(s) using the same techniques as above and the formula \( \phi_{G(F)}|_K = \inf_{G(k)} \phi_{G(k)} \).

Let \( \pi(\theta') \in \widehat{G(k)} \) be cuspidal. If \( \lambda \in \hat{T(F)} \) and \( \bar{\lambda} \in \hat{T(k)} \), such that \( \lambda|_{T(\sigma_F)} = \inf_{T(k)} \bar{\lambda} \), then Lemma 4.4 implies:

\[
\text{Hom}_{G(F)}(\text{c-Ind}_{K}^{G(F)} \pi(\theta'), \text{Ind}_{Z_k}^{G(F)} \lambda) = \text{Hom}_{B(k)}(\pi(\theta'), \bar{\lambda}) \subseteq \text{Hom}_{U(k)}(\pi(\theta'), \bar{\lambda}),
\]

where \( U(k) \) is the unipotent radical of \( B(k) \). Now \( \bar{\lambda} \) is trivial on \( U(k) \) and \( \pi(\theta') \) does not contain the trivial character on \( U(k) \), since it is cuspidal. Hence the last expression is equal 0. Therefore \((4, 1) = 0 \) follows by taking \( \lambda = \chi \) and \((4, 2), (4, 3) = 0 \) follow from (4.2) by taking \( \lambda = \phi_{T(F)} \).

This finishes the proof for the first three columns.

Now we consider the last column. \( \varrho \) is cuspidal and of level 0, hence \( \varrho = \text{c-Ind}_{Z_K}^{G(F)} \Lambda \) where \( \Lambda|_K = \bar{\varrho} \) is an inflation of a (unique up to isomorphism) cuspidal representation \( \bar{\varrho} \) of \( G(k) \) (this follows from [14] 14.5 Theorem and 11.5 Theorem). If \( 0 \neq \text{Hom}_{G(F)}(\text{c-Ind}_{Z_K}^{G(F)} \pi, \varrho) = \text{Hom}_{G(F)}(\pi, \varrho) \), then \( \pi \) and \( \bar{\varrho} \) both occur in \( \varrho \), hence by loc.cit. 11.1 Proposition 1 they must intertwine in \( G(F) \). Thus by loc.cit. 11.5 Lemma, \( \pi \cong \bar{\varrho} \) and in particular \( \pi \) is cuspidal. Hence \((1, 4) = (2, 4) = (3, 4) = 0 \). The next lemma finishes the proof. \( \square \)

**Lemma 4.5.** Let \( \pi \in \widehat{G(k)} \) be cuspidal and denote again by \( \pi \) its inflation to \( K \). Let \( \Lambda \) be some extension of \( \pi \) to \( ZK \). Then

\[
\text{Hom}_{G(F)}(\text{c-Ind}_{K}^{G(F)} \pi, \text{c-Ind}_{Z_K}^{G(F)} \Lambda) = \underline{\mathbb{Q}_l}.
\]

**Proof.** Write \( I^{(n)} := K \cap t^{(0,n)}Kt^{(0,-n)} \), and \( (n)\pi(g) := \pi(t^{(0,-n)}gt^{(0,n)}) \) for \( n \geq 0 \) and \( g \in t^{(0,n)}Kt^{(0,-n)} \) (in particular \( I^{(0)} = K \)). Frobenius reciprocity and the Mackey formula imply:

\[
\text{Hom}_{G(F)}(\text{c-Ind}_{K}^{G(F)} \pi, \text{c-Ind}_{Z_K}^{G(F)} \Lambda) = \text{Hom}_{K}(\pi, \text{c-Ind}_{Z_K}^{G(F)} \Lambda)|_K = \text{Hom}_{K}(\pi, \bigoplus_{n \geq 0} \text{Ind}_{I^{(n)}}^{K}(n)\pi) = \text{End}_{K}(\pi) \oplus \bigoplus_{n \geq 1} \text{Hom}_{I^{(n)}}(\pi, (n)\pi).
\]

Now Schur’s lemma for the compact group \( K \) implies \( \text{End}_{K}(\pi) = \underline{\mathbb{Q}_l} \), since \( \pi \) is irreducible, and we have to show \( \text{Hom}_{I^{(n)}}(\pi, (n)\pi) = 0 \) for \( n \geq 1 \). In fact, consider the subgroup \( N = \{ \left( \begin{array}{cc} 1 & 0 \\ at^n & 1 \end{array} \right) : a \in k \} \) of \( I^{(n)} \). Since \( N \) is in the kernel of \( K \to G(k) \) and since \( \pi \) is inflated from \( G(k) \), the restriction of \( \pi \) to \( N \) is trivial. But \( (n)\pi(\left( \begin{array}{cc} 1 & 0 \\ at^n & 1 \end{array} \right)) = \pi(\left( \begin{array}{cc} 1 & 0 \\ a & 1 \end{array} \right)) \) and \( \pi \) is cuspidal, hence \((n)\pi \) does not contain the trivial character on \( N \), and the claim follows. \( \square \)
Remark 4. Let \( \pi \) be any representation of \( G(k) \). The representation \( \operatorname{c-Ind}_K^{G(F)} \pi \) is very big. More precise, put \( I^{(n)} := K \cap t(0,n)K t(0,\ast -n) \) (in particular, \( I^{(0)} = K \) and \( I^{(1)} = I \)) and \( (n) \pi(g) := \pi(t(0,\ast -n)gt(0,n)) \) for \( g \in t(0,n)K t(0,\ast -n) \). Then the Mackey formula implies:

\[
(\operatorname{c-Ind}_K^{G(F)} \pi)|_K \cong \bigoplus_{n \geq 0} \operatorname{Ind}_I^{K} (n) \pi.
\]

In particular, \( \operatorname{c-Ind}_K^{G(F)} \pi \) is not admissible: its restriction to \( K \) contains \( \mathbb{Z} \) copies of \( \pi \).

4.3. Case \( b \) regular semisimple.

Proposition 4.6. Let \( b = t(0,\alpha) \) with \( \alpha > 0 \), \( w \in \hat{W} \), such that \( X_w(b) \neq 0 \) and let \( w_a \in W_a \) with \( w = w_a b_1^a \) and \( m \) as in \((3.1)\). Let \( \theta \in T(w)_\text{aff}/T_1 \).

(i) If \( \ell(w_a) = \alpha \), then \( T(w)_\text{aff}/T_1 = T(k) \). Let \( \hat{\theta} \) be equal \( \theta \) if condition \((3.2)\) is true, and equal \( \theta^q \) otherwise, where \( 1 \neq v \in W \). Write \( \hat{\theta}_{T(\sigma_F)} = \operatorname{infl}_{T(k)}^{T(\sigma_F)} \hat{\theta} \) (inflation via \( p_0 \)). Then

\[
R^0_b(w)_\text{aff} = \operatorname{c-Ind}_{T(\sigma_F)}^{T(F)} \hat{\theta}_{T(\sigma_F)}.
\]

(ii) If \( \ell(w_a) > \alpha \), then \( T(w)_\text{aff}/T_1 \cong k^* \). If \( \theta = \theta^q \), denote again by \( \theta \) the character induced on \( k^* \) via \( \det: T(w)_\text{aff}/T_1 \to k^* \) and by \( \theta_{T(\sigma_F)} \) its inflation via \( T(\sigma_F) \xrightarrow{p_m} T(k) \xrightarrow{\det} k^* \) to \( T(\sigma_F) \) (note that \( \theta_{T(\sigma_F)} \) is independent of \( m \)). Then:

\[
R^0_b(w)_\text{aff} = 0,
\]

\[
H^1_c(\hat{X}_w(b), \mathbb{Q}_l)_\theta = \begin{cases} 
\operatorname{c-Ind}_{T(\sigma_F)}^{T(F)} \theta_{T(\sigma_F)}(\ell(w) - \alpha - 1) & \text{if } r = \ell(w) - \alpha > 0 \\
\operatorname{c-Ind}_{T(\sigma_F)}^{T(F)} \theta_{T(\sigma_F)}(\ell(w) - \alpha - 3) & \text{if } r = \ell(w) - \alpha + 1 > 0 \\
0 & \text{otherwise,}
\end{cases}
\]

where \( \hat{w} \) is a preimage of \( w \) in \( \hat{W}_1 \).

Proof. Denote by \( \hat{w} \) a preimage of \( w \) in \( \hat{W}_1 \). Let first \( \ell(w_a) = \alpha \). By Theorem 3.3, \( \hat{X}_w(b) \) is a disjoint union of points with stabilizers of a point equal \( T_1 \) in \( T(F) \). As in Lemma 4.1, we have

\[
H^0_c(\hat{X}_w(b), \mathbb{Q}_l) = \operatorname{c-Ind}_{T(\sigma_F)}^{T(F)} \operatorname{Ind}_{T_1}^{T(\sigma_F)} 1_{\mathbb{Q}_l} = \bigoplus_{\theta \in T(k)} \operatorname{c-Ind}_{T(\sigma_F)}^{T(F)} \theta_{T(\sigma_F)},
\]

as \( T(F) \)-representations. If condition \((3.2)\) is true (i.e. \( w_a C^0 = C^0 \)), \( K_b^{(m)} = T(0,F) = T(w)_\text{aff} \) act in the same way on \( \hat{X}_w(b) \) and hence

\[
R^0_b(w)_\text{aff} = H^1_c(\hat{X}_w(b), \mathbb{Q}_l)_\theta = \operatorname{c-Ind}_{T(\sigma_F)}^{T(F)} \theta.
\]

If \((3.2)\) fails to be true (i.e. \( w_a C^0 = C^{-\alpha} \)), the action of \( T(\sigma_F) \) is the same and the torus action is twisted by the non-trivial element of \( W \). This proves (i). Assume now \( \ell(w_a) > \alpha \). The statement about \( R^0_b(w)_\text{aff} \) follows from the statement about \( H^1_c(\hat{X}_w(b), \mathbb{Q}_l)_\theta \). First of all we have:

\[
H^1_c(\hat{S}(b,w), \mathbb{Q}_l)_\theta = \begin{cases} 
\theta_{T(\sigma_F)} & \text{if } \theta = \theta^q \text{ and } r = 1 \\
\theta_{T(\sigma_F)}(-1) & \text{if } \theta = \theta^q \text{ and } r = 2 \\
0 & \text{otherwise,}
\end{cases}
\]

where \((-1)\) means the Tate twist. In fact, one applies the Mayer-Vietoris sequence to the inclusions \( \mathbb{G}_m \hookrightarrow \mathbb{P}^1 \hookrightarrow \{0, \infty\} \) to compute the cohomology of \( \mathbb{G}_m \). In both degrees \((r = 1, 2)\) with non-vanishing cohomology, the representations \( H^r_c(\mathbb{G}_m, \mathbb{Q}_l) \) of the stabilizers in \( p_m(K_b^{(m)}) = T(k) \) and in \( T(w)_\text{aff} \) of a (hence any) connected component of \( \hat{S}(b,w) = \bigsqcup_{K} \mathbb{G}_m \) are trivial. Therefore \( H^1_c(\bigsqcup_{K} \mathbb{G}_m, \mathbb{Q}_l) = \bigoplus_{\theta \in k^*} \theta \) as \( k^* \)-representation (the \( k^* \)-action on the connected components is defined as the quotient of the action of \( T(k) \) or, equivalently, of \( T(w)_\text{aff}/T_1 \)).
Now (4.4) follows, since for any \( \theta \in T(w)_\text{aff}/T_1 \), we have: \( \theta \) factors through \( T(w)_\text{aff}/T_1 \to k^* \Leftrightarrow \theta = \text{theta}^\circ \). From (4.4) and Lemma 4.1, the second statement in (ii) follows. 

4.4. Case \( b = b_1 \).

Recall that \( J_{b_1} = D^* \) where \( D \) is the central quaternion algebra over \( F \), and \( \Lambda_{b_1} = U_D \) is the group of units in the valuation ring of \( D \). Recall that \( p_m' \) is \( p_m \) composed with projection \( B(\hat{k}) \to T(\hat{k}) \) and that for \( m \in \{0,1\} \) and \( w \in \hat{W} \) with non-trivial image in \( W \), the images of \( U_D \) 's being conjugate by elements of \( T(w)_\text{aff}/T_1 \) coincide. If \( \theta \in T(w)_\text{aff}/T_1 \), denote by \( \theta_{U_D} \) the inflation of \( \theta \) via \( p_m' \) to \( U_D \).

**Proposition 4.7.** Let \( w \in \hat{W} \), such that \( X_w(b_1) \neq \emptyset \). Then \( T(w)_\text{aff}/T_1 \cong k^* \).

Let \( \pi \in T(w)_\text{aff}/T_1 \). Then

\[
R_{b_1}(w)_{\text{aff}} = \text{c-Ind}_{U_D}^D \theta_{U_D}.
\]

**Proof.** Every \( w \) with \( X_w(b_1) \neq \emptyset \) has non-trivial image in \( W \), hence the first statement. As in part (i) of Proposition 4.6, it follows that \( R_{b_1}(w)_{\text{aff}} = H_c(\bar{X}_w(b_1), \bar{\psi}) \) is either \( \text{c-Ind}_{U_D}^D \theta_{U_D} \) or \( \text{c-Ind}_{U_D}^D(\theta^0)_{U_D} \), depending on the condition \( (3.2) \). The next lemma finishes the proof, since \( (\theta^0)_{U_D}(u) = \theta_{U_D}(b_1u^{-1}) \) for \( u \in U_D \).

**Lemma 4.8.** Let \( \chi \) be a character of \( U_D \), and set \( \chi'(u) = \chi(b_1u^{-1}) \) for \( u \in U_D \). Then: \( \text{c-Ind}_{U_D}^D \chi \cong \text{c-Ind}_{U_D}^D \chi' \).

**Proof.** The functions \( f_i : D^* \to \overline{\mathbb{Q}_l} \), with \( \text{supp}(f_i) = U_Db_1^i \) and \( f_i(ub_1^i) = \chi(u) \) for \( u \in U_D \), resp. \( f_i^\sigma : D^* \to \overline{\mathbb{Q}_l} \), with \( \text{supp}(f_i^\sigma) = U_Db_1^i \) and \( f_i^\sigma(ub_1^i) = \chi^\sigma(u) \) define a basis of \( \text{c-Ind}_{U_D}^D \chi \) resp. of \( \text{c-Ind}_{U_D}^D \chi' \). An element \( h = vb_1^i \) with \( v \in U_D \) acts on \( f_i \) by \( h.f_i = \chi(b_1^{-1}vb_1^{-1})f_i \), and analogously on \( f_i^\sigma \). It is easy to see that \( f_i \mapsto f_i^\sigma \) gives a \( D^* \)-isomorphism between the two representations.

The lemma also implies that \( \text{c-Ind}_{U_D}^D \theta_{U_D} \) depends only on \( \theta \) and not on \( m \).

If \( \phi \in \hat{F}^* \), then \( \phi_D := \phi \circ \det \) is a character of \( D^* \), and every character of \( D^* \) is obtained by this construction. Let \( \pi \) be a smooth reducible representation of \( D^* \). The level \( \ell(\pi) \) of \( \pi \) is the least non-negative integer \( n \), such that \( \pi \) is trivial on \( (n+1) \)-units \( U_D^{n+1} \) of \( D \).

**Lemma 4.9.** Let \( \pi \in \hat{D}^* \) containing the trivial character on \( U_D^n \) \( (n \geq 1) \). Then \( \ell(\pi) < n \).

**Proof.** Let \( \ell(\pi) = m \). Then \( \pi \) is trivial on \( U_D\cap U_D^{(m+1)} \), hence \( \pi|\overline{U_D} \cong \bigoplus \psi_i \), where \( \psi_i \) are characters. By \( \Pi \) 11.1 Proposition 1, \( \psi_i \) intertwin in \( D^* \), and since \( U_D \) is normal in \( D^* \), it is equivalent to \( \psi_i \)'s being conjugate by elements of \( D^* \). If \( m \geq n \), then one of \( \psi_i \)'s would be trivial, and since they are all conjugate, each of them would be trivial, i.e. \( \pi \) would be trivial on \( U_D^n \), which would imply \( \ell(\pi) < m \), a contradiction.

The representations of \( D^* \) of level 0 and dimension > 1 are parametrized by admissible pairs \( (E/F, \chi) \) of level zero in the following way: for the unramified extension \( E/F \) of degree two contained in \( L \), fix an embedding \( E^* \to D^* \) (all such are conjugate in \( D^* \)). Extend any \( \chi \in \hat{E}^* \) of level zero by triviality to a character \( \Xi \) of \( E^*U_D \). The map \( \chi \mapsto \pi(\Xi) := \text{c-Ind}_{E^*U_D}^{D^*} \Xi \) defines an one-to-one bijection between the set of all characters of \( E^* \) with \( \chi|_{U_E} \neq \chi^0|_{U_E} \) of level zero modulo the equivalence relation \( \chi \sim \chi^0 \) and all irreducible representations of \( D^* \) of level zero and dimension > 1 (this is \( \Pi \) 54.2 Proposition).

**Theorem 4.10.** Let \( \theta = \theta^\circ \) and put \( \theta_{U_D} := \inf_{k^*} \theta \) (inflation via \( p_0 \)). Let \( \pi \in \hat{D}^* \).

(i) If \( \theta = \theta^0 \), then

\[
\text{Hom}_{D^*}(\text{c-Ind}_{U_D}^U \theta_{U_D}, \pi) = \begin{cases} 
\bigoplus \psi_i & \text{if } \pi \text{ is a character of level 0 and } \pi|_{U_D} = \theta_{U_D}, \\
0 & \text{otherwise}.
\end{cases}
\]
(ii) If $\theta \neq \theta^q$, then
\[
\text{Hom}_{D^*}(\text{c-Ind}^{D^*}_{U^*_D} \theta_{U^*_D}, \pi) = \begin{cases}
\mathbb{Q}_L & \text{if } \pi = \pi(\Xi) \text{ with } \Xi|_{U_D} = \theta_{U^*_D} \text{ or } \Xi^q|_{U_D} = \theta_{U^*_D}, \\
0 & \text{otherwise.}
\end{cases}
\]

Proof. First of all we have
\[
\text{Hom}_{D^*}(\text{c-Ind}^{D^*}_{U^*_D} \theta_{U^*_D}, \pi) = \text{Hom}_{U_D}(\theta_{U_D}, \pi).
\] (4.5)
It follows that if the space on the left is non-zero, then $\pi$ must contain the trivial character on $U^1_D$. Hence Lemma 4.9 implies $\ell(\pi) = 0$.

Let first $\pi$ be a character. Then the Hom-space above is non-zero if and only if $\theta_{U_D} = \pi|_{U_D}$. Now, $\theta_{U_D}$ factors as $\theta \circ p'_0: U_D \to k^* \to \overline{\mathbb{Q}_L}$, and since $\pi$ has level 0, it factors as $\pi \circ \det: U_D \to U_F \xrightarrow{\rho} k^* \xrightarrow{\bar{\pi}} \overline{\mathbb{Q}_L}$. Since $N_{k^*/k} \circ p'_0 = \rho \circ \det: U_D \to k^*$, and since $p'_0$ is an epimorphism, it follows that $\theta = \bar{\pi} \circ N_{k^*/k}$. In particular, $\theta$ factors through the norm, which is equivalent to $\theta = \theta^q$.

Now assume $\pi = \pi(\Xi) = \text{c-Ind}^{E^*_U U^*_D}_{E^*_U U^*_D} \Xi$ with $\Xi$ trivial on $U^*_D$ and $\Xi|_{U^*_D} \neq \Xi^q|_{U^*_D}$. We have $U_D \subseteq E^*_U U^*_D$ and both are normal in $D^*$. The $(E^*_U U^*_D, U_D)$-double cosets in $D^*$ are just left $E^*_U U^*_D$-cosets and there are exactly two of them, represented by 1 and $b_1$. Hence the Mackey formula implies: $\pi|_{U_D} = (\text{c-Ind}^{E^*_U U^*_D}_{E^*_U U^*_D} \Xi)|_{U_D} = \Xi|_{U_D} \oplus \Xi^q|_{U_D}$. From this and (4.5) the theorem follows.

Remark 5. With the same assumptions as in Proposition 4.7, taking additionally $w \neq b_1$ and $\theta 
eq \theta^q$, let $\Xi$ be a character on $E^*_U U^*_D$, trivial on $U^*_D$ and on the uniformizer $t^{(1,1)}$ of $E$ and such that $\Xi|_{U_D} = \theta \circ p$, where $p: U_E \to k^*$ is the reduction modulo $p$ map. From Lemma 4.1(ii), using $Z U_D = E^*_U U_D = E^*_U U^*_D$ we obtain (condition (3.2) is irrelevant since $\pi(\Xi) = \pi(\Xi^q)$):
\[
R_{b_1}(w)_{\text{aff}, PGL} = \pi(\Xi).
\]

In particular, these representations are admissible.

Acknowledgements. This paper is an extension of the author’s diploma thesis, written in 2009 at the University of Bonn, under supervision of Prof. Rapoport and Prof. Görtz. The author is very grateful to both of them for the supervision of the thesis and to Ulrich Görtz for his continuous support, interest in the work and many helpful remarks afterwards.
